

# COMP 3331/9331: Computer Networks and Applications

Week 8

Control Plane (Routing)

**Chapter 5: Section 5.1 – 5.2, 5.6**

# Network layer, control plane: outline

## 5.1 introduction

### 5.2 routing protocols

- ❖ link state
- ❖ distance vector
- ❖ Hierarchical routing (NOT ON EXAM)

### 5.6 ICMP: The Internet Control Message Protocol

# Network-layer functions

- **forwarding**: move packets from router's input to appropriate router output
- **routing**: determine route taken by packets from source to destination

*data plane*

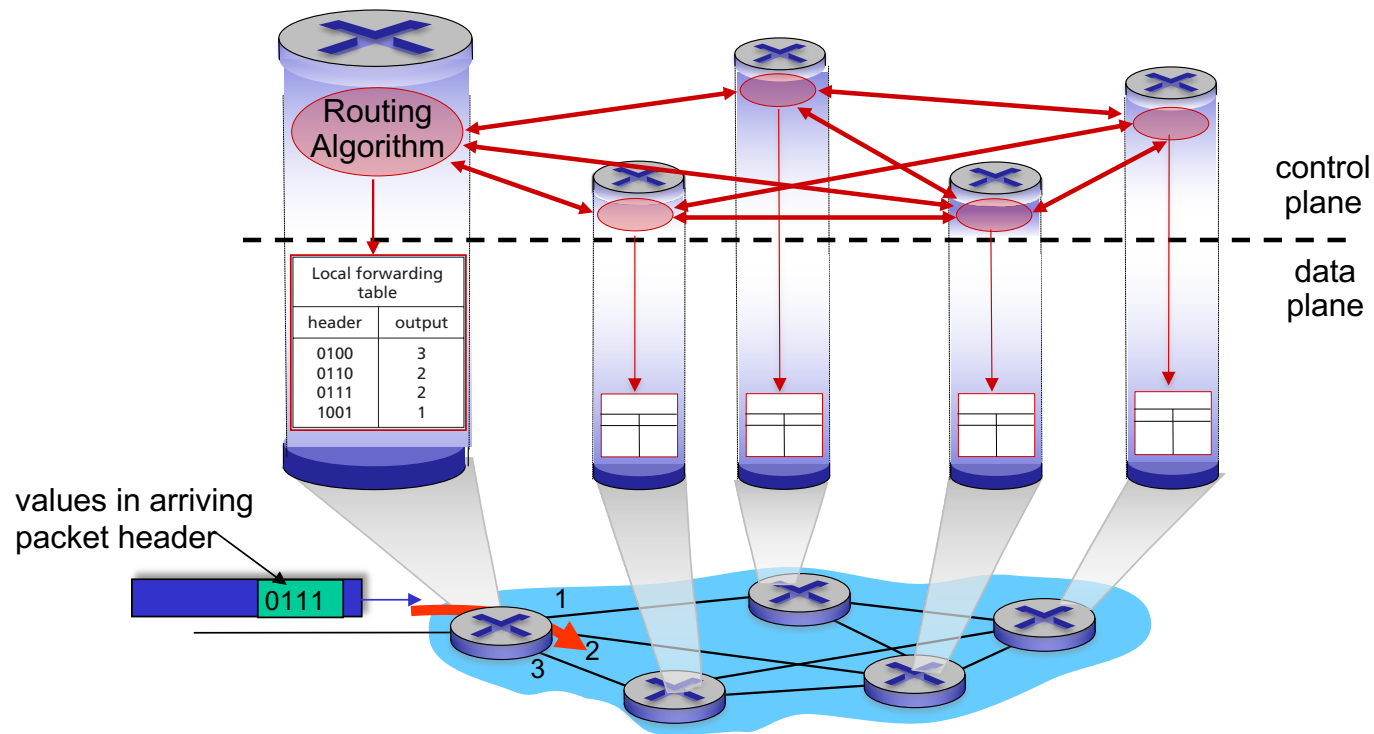

*control plane*

## Two approaches to structuring network control plane:

- ❖ per-router control (traditional)
- ❖ logically centralized control (software defined networking)

# Per-router control plane

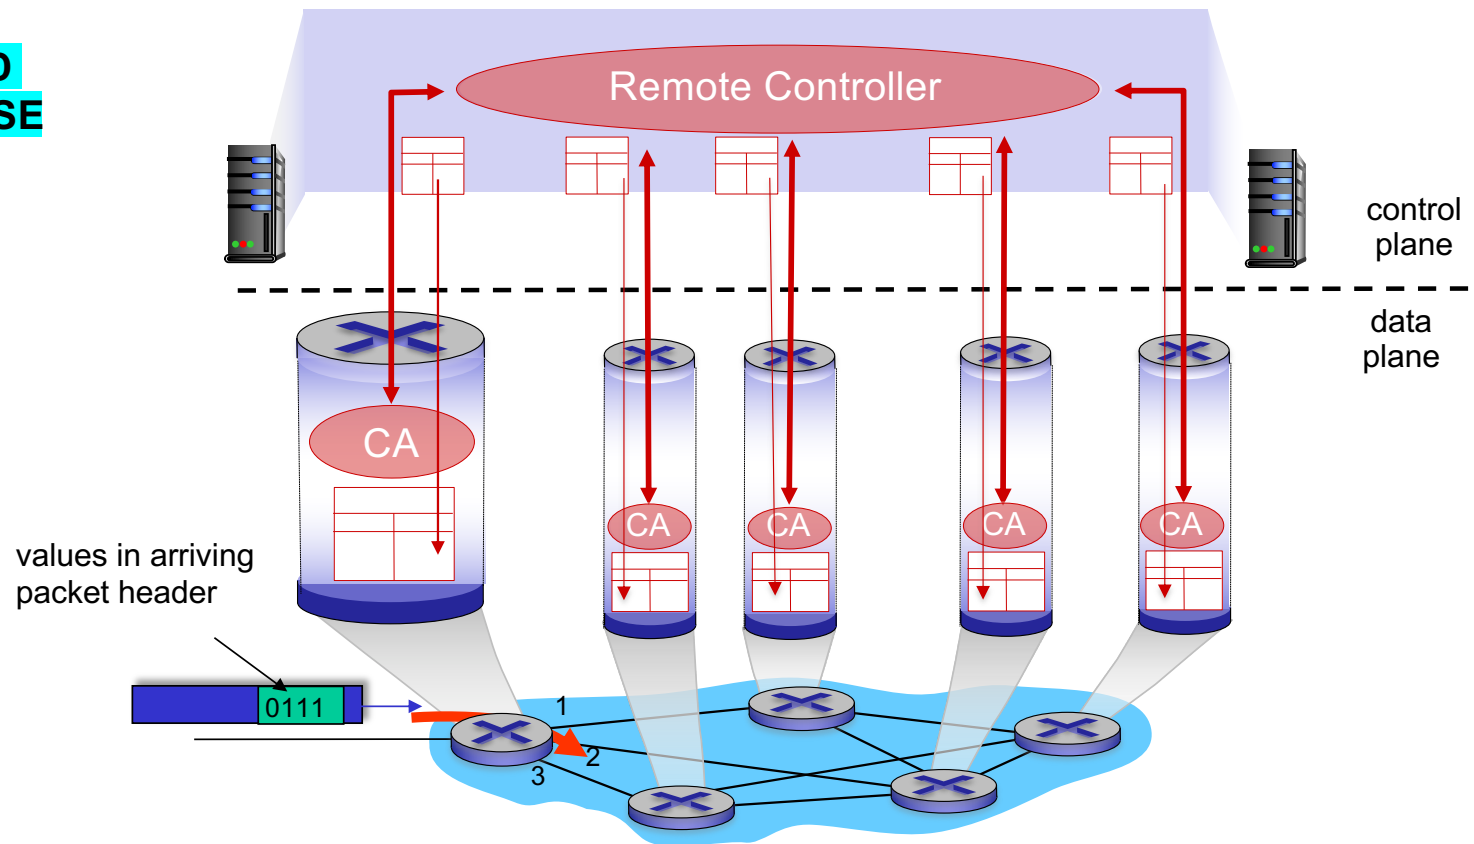

Individual routing algorithm components *in each and every router* interact in the control plane

# Software-Defined Networking (SDN) control plane

Remote controller computes, installs forwarding tables in routers

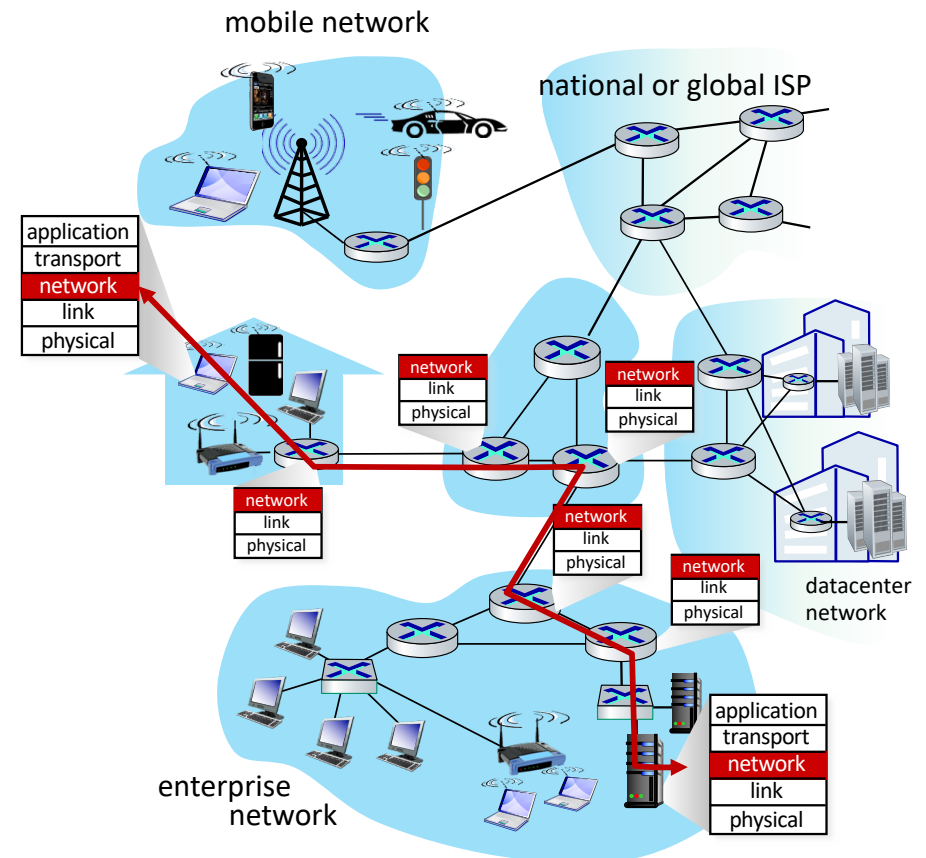

**NOT COVERED  
IN THIS COURSE**

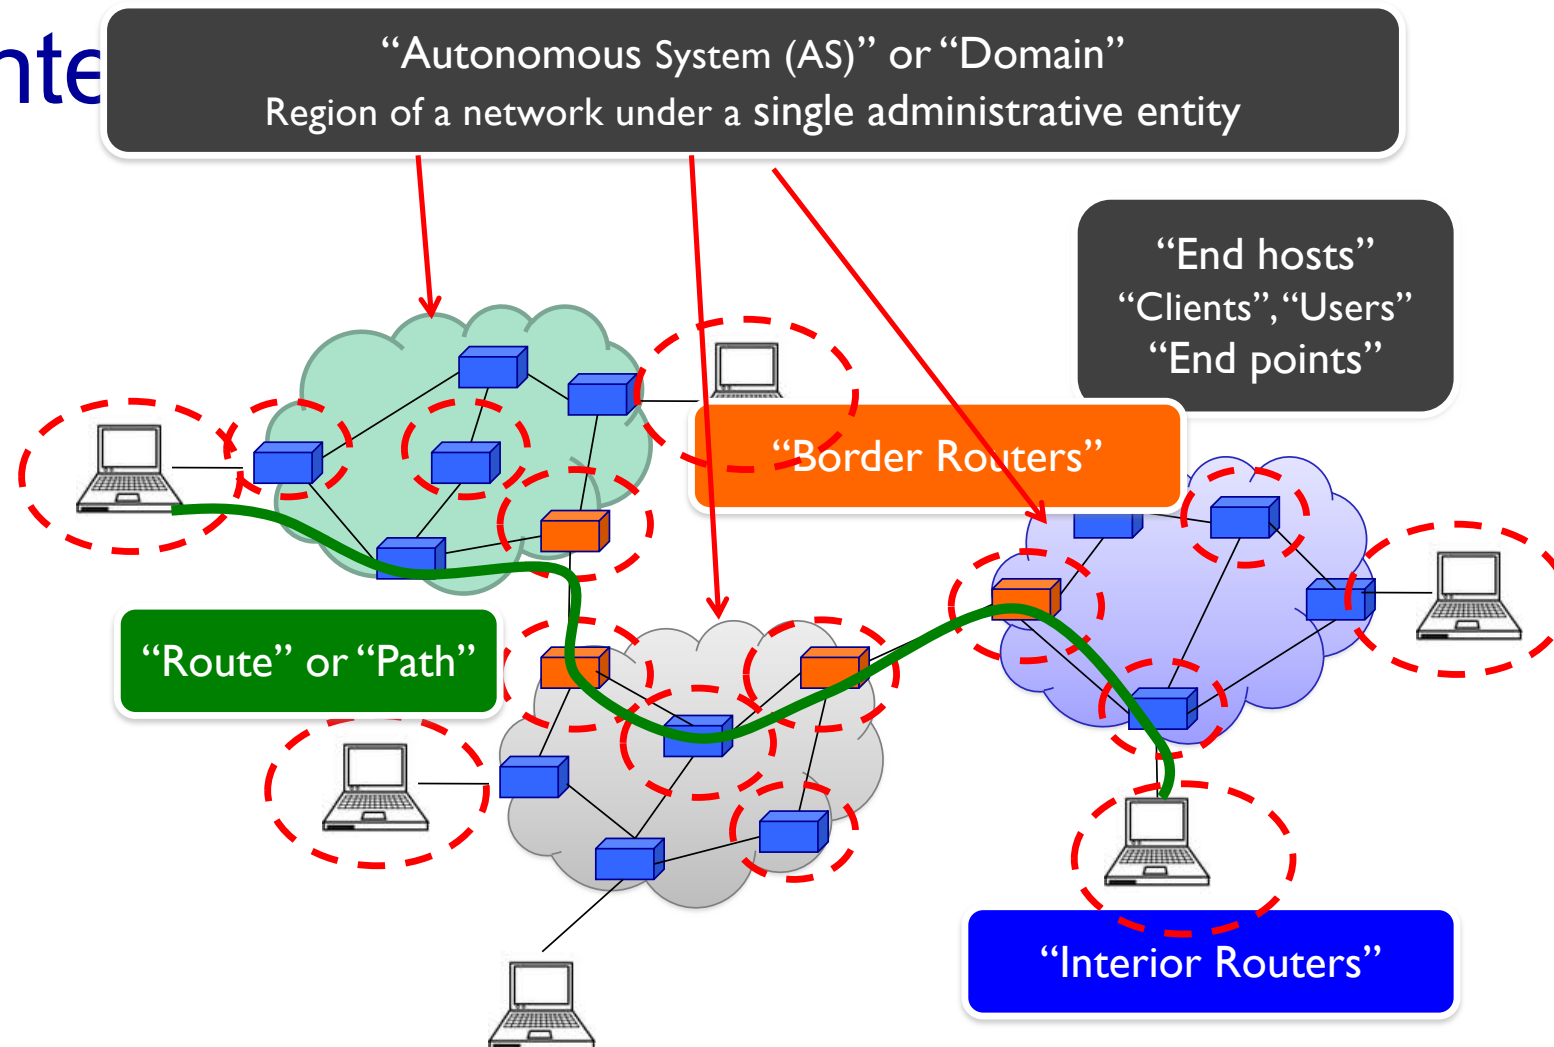

# Routing protocols

**Routing protocol goal:** determine “good” paths (equivalently, routes), from sending hosts to receiving host, through network of routers

- ❖ **path:** sequence of routers packets traverse from given initial source host to final destination host
- ❖ **“good”:** least “cost”, “fastest”, “least congested”
- ❖ routing: a “top-10” networking challenge!

# Conte

# Internet Routing

- ❖ Internet Routing works at two levels
- ❖ Each AS runs an **intra-domain** routing protocol that establishes routes within its domain
  - AS -- region of network under a single administrative entity
  - Link State, e.g., Open Shortest Path First (OSPF)
  - Distance Vector, e.g., Routing Information Protocol (RIP)
- ❖ ASes participate in an **inter-domain** routing protocol that establishes routes between domains
  - Path Vector, e.g., Border Gateway Protocol (BGP)

# Graph abstraction: link costs

$c_{a,b}$ : cost of *direct* link connecting  $a$  and  $b$   
e.g.,  $c_{w,z} = 5$ ,  $c_{u,z} = \infty$

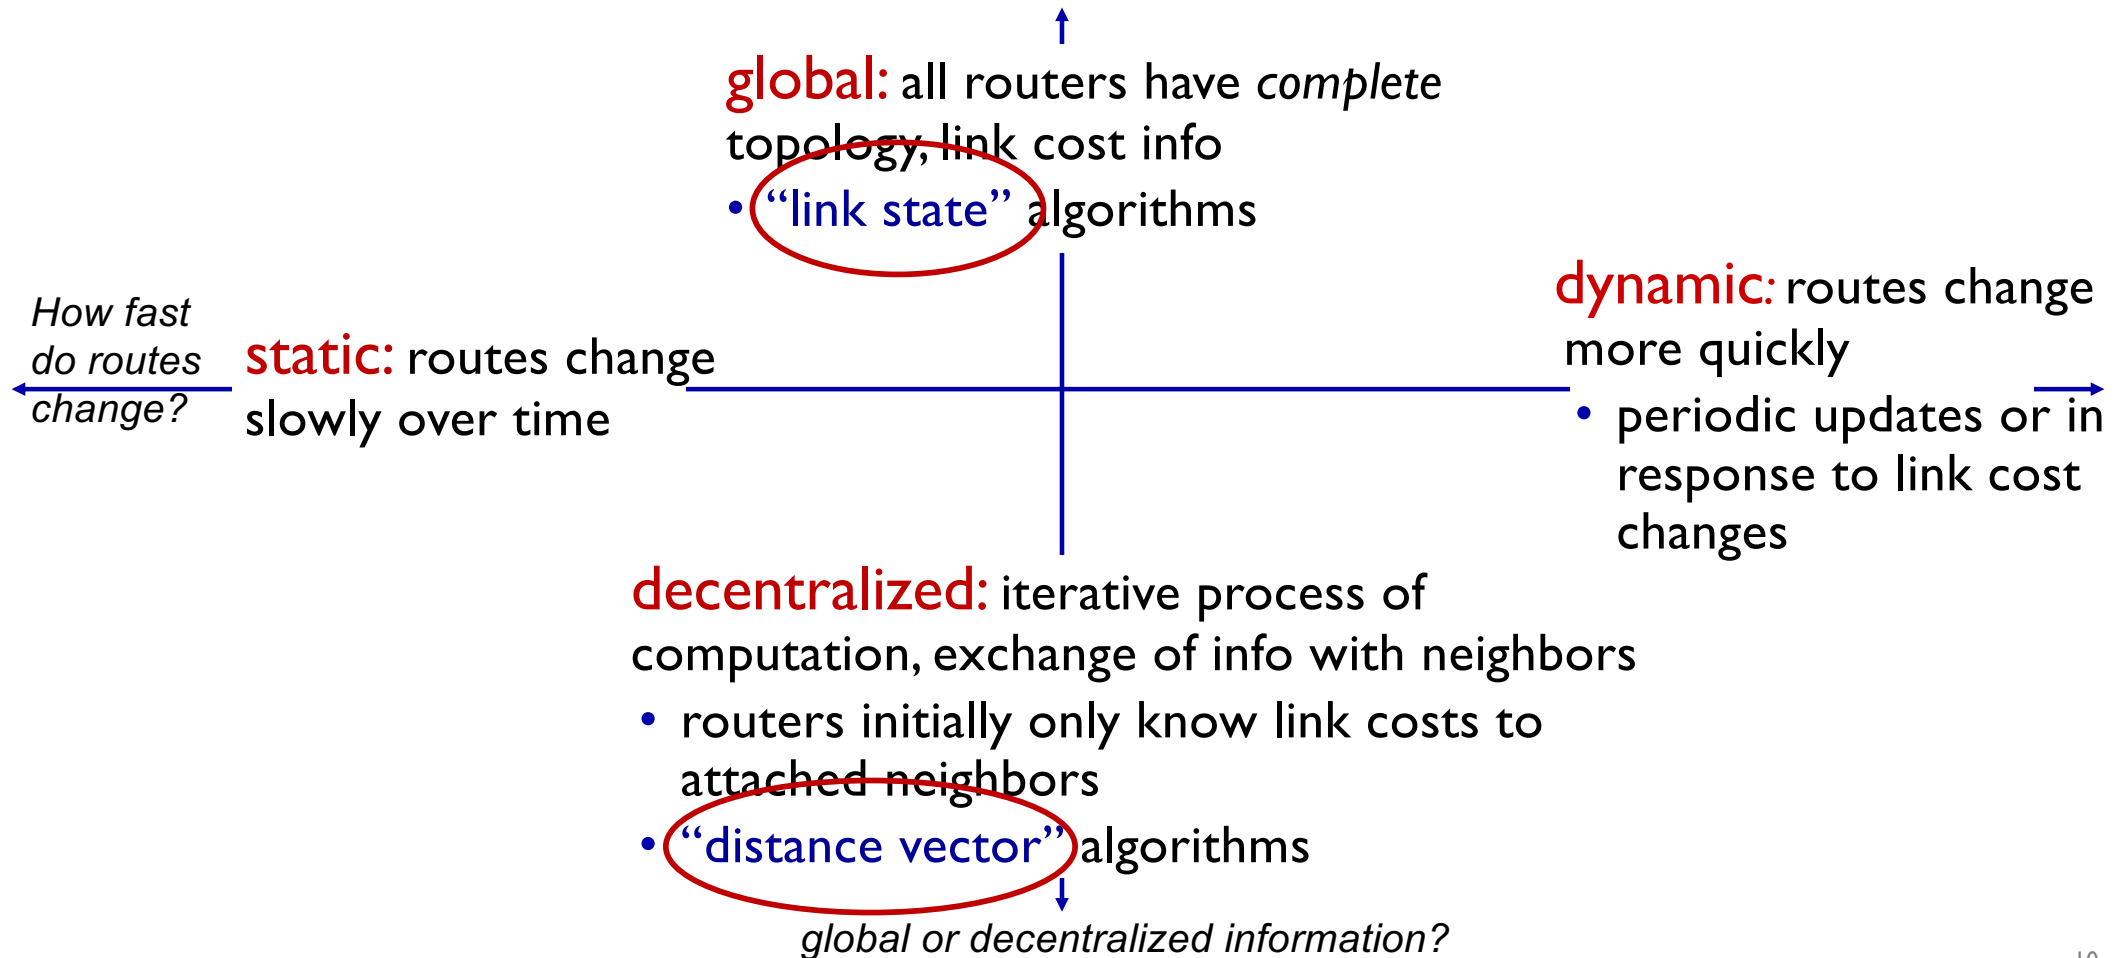

cost defined by network operator:  
could always be 1, or inversely  
related to bandwidth, or inversely  
related to congestion

graph:  $G = (N, E)$

$N$ : set of routers =  $\{ u, v, w, x, y, z \}$

$E$ : set of links =  $\{ (u,v), (u,x), (v,x), (v,w), (x,w), (x,y), (w,y), (w,z), (y,z) \}$

# Routing algorithm classification

# Network layer, control plane: outline

5.1 introduction

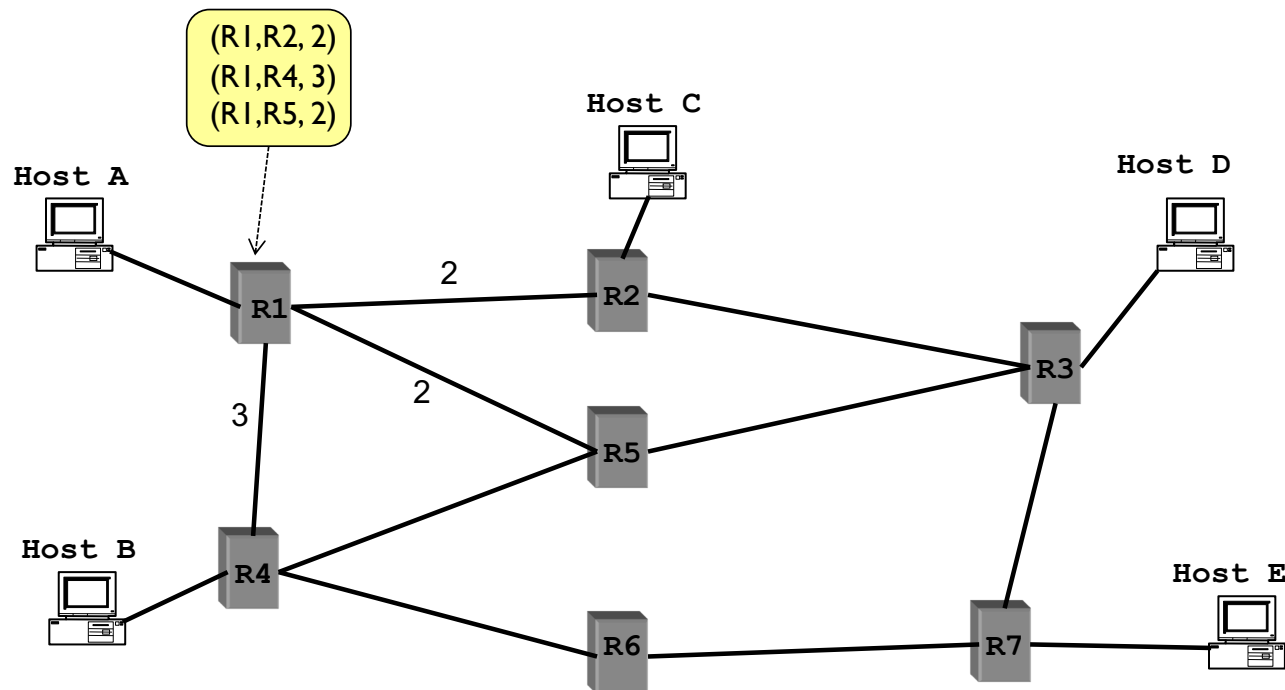

5.2 routing protocols

- ❖ link state
- ❖ distance vector
- ❖ hierarchical routing

5.6 ICMP: The Internet Control  
Message Protocol

# Link State Routing

- ❖ Each node maintains its **local** “link state” (LS)
  - i.e., a list of its directly attached links and their costs

# Link State Routing

- ❖ Each node maintains its local “link state” (LS)
- ❖ Each node floods its local link state
  - on receiving a **new** LS message, a router forwards the message to all its neighbors other than the one it received the message from

# Flooding LSAs

- ❖ Routers transmit **Link State Advertisement (LSA)** on links
  - A neighbouring router forwards out on all links except incoming
  - Keep a copy locally; don't forward previously-seen LSAs
- ❖ Challenges
  - Packet loss
  - Out of order arrival
- ❖ Solutions
  - Acknowledgements and retransmissions
  - Sequence numbers
  - Time-to-live for each packet

# Link State Routing

- ❖ Each node maintains its local “link state” (LS)
- ❖ Each node floods its local link state
- ❖ Eventually, each node learns the entire network topology
  - Can use Dijkstra's to compute the shortest paths between nodes

# Dijkstra's link-state routing algorithm

- **centralized:** network topology, link costs known to *all* nodes
  - accomplished via “link state broadcast”
  - all nodes have same info
- computes least cost paths from one node (“source”) to all other nodes
  - gives *forwarding table* for that node
- **iterative:** after  $k$  iterations, know least cost path to  $k$  destinations

## notation

- $c_{x,y}$ : direct link cost from node  $x$  to  $y$ ;  $= \infty$  if not direct neighbors
- $D(v)$ : *current* estimate of cost of least-cost-path from source to destination  $v$
- $p(v)$ : predecessor node along path from source to  $v$
- $N'$ : set of nodes whose least-cost-path *definitively* known

# Dijkstra's link-state routing algorithm

```
1  Initialization:
2   $N' = \{u\}$                                 /* compute least cost path from u to all other nodes */
3  for all nodes v
4      if v adjacent to u                        /* u initially knows direct-path-cost only to direct neighbors */
5          then  $D(v) = c_{u,v}$                     /* but may not be minimum cost! */
6      else  $D(v) = \infty$ 
7
8  Loop
9      find w not in  $N'$  such that  $D(w)$  is a minimum
10     add w to  $N'$ 
11     update  $D(v)$  for all v adjacent to w and not in  $N'$  :
12          $D(v) = \min ( D(v), D(w) + c_{w,v} )$ 
13         /* new least-path-cost to v is either old least-cost-path to v or known
14         least-cost-path to w plus direct-cost from w to v */
15 until all nodes in  $N'$ 
```

## Example: Dijkstra's Algorithm

3	ADEB					
4	ADEBC					
5	ADEBCF					

To determine path  $A \rightarrow C$  (say),  
work backward from C via  $p(v)$

# Example: Dijkstra's Algorithm

resulting least-cost-path tree from A:

resulting forwarding table in A:

destination	outgoing link
B	(A,B)
C	(A,D)
D	(A,D)
E	(A,D)
F	(A,D)

route from A to B directly

route from A to all other destinations via D

# Dijkstra's algorithm: another example

Step	$N'$	$D(v), p(v)$	$D(w), p(w)$	$D(x), p(x)$	$D(y), p(y)$	$D(z), p(z)$
0	u	7,u	3,u	5,u	$\infty$	$\infty$
1	uw	6,w		5,u	11,w	$\infty$
2	uwx	6,w			11,w	14,x
3	uwxv				10,v	14,x
4	uwxvy					12,y
5	uwxvyz					

## notes:

- construct least-cost-path tree by tracing predecessor nodes
- ties can exist (can be broken arbitrarily)

# Dijkstra's algorithm: discussion

**algorithm complexity:**  $n$  nodes

- each of  $n$  iteration: need to check all nodes,  $w$ , not in  $N$
- $n(n+1)/2$  comparisons:  $O(n^2)$  complexity
- more efficient implementations possible:  $O(n \log n)$

**message complexity:**

- each router must *broadcast* its link state information to other  $n$  routers
- efficient (and interesting!) broadcast algorithms:  $O(n)$  link crossings to disseminate a broadcast message from one source
- each router's message crosses  $O(n)$  links: overall message complexity:  $O(n^2)$

# Dijkstra's algorithm: oscillations possible

- when link costs depend on traffic volume, **route oscillations** possible
- sample scenario:
  - routing to destination a, traffic entering at d, c, e with rates  $I, e (< I), I$
  - link costs are directional, and volume-dependent

initially

given these costs,  
find new routing....  
resulting in new costs

given these costs,  
find new routing....  
resulting in new costs

given these costs,  
find new routing....  
resulting in new costs

# Network layer, control plane: outline

5.1 introduction

5.2 routing protocols

- ❖ link state
- ❖ distance vector
- ❖ hierarchical routing

5.6 ICMP: The Internet Control  
Message Protocol

# Distance vector algorithm

Based on *Bellman-Ford* (BF) equation (dynamic programming):

Bellman-Ford equation

Let  $D_x(y)$ : cost of least-cost path from  $x$  to  $y$ .

Then:

$$D_x(y) = \min_v \{ c_{x,v} + D_v(y) \}$$

$\min$  taken over all neighbors  $v$  of  $x$

direct cost of link from  $x$  to  $v$

$v$ 's estimated least-cost-path cost to  $y$

# Bellman-Ford Example

Suppose that  $u$ 's neighboring nodes,  $x, v, w$ , know that for destination  $z$ :

Bellman-Ford equation says:

$$\begin{aligned} D_u(z) &= \min \{ c_{u,v} + D_v(z), \\ &\quad c_{u,x} + D_x(z), \\ &\quad c_{u,w} + D_w(z) \} \\ &= \min \{ 2 + 5, \\ &\quad 1 + 3, \\ &\quad 5 + 3 \} = 4 \end{aligned}$$

*node achieving minimum ( $x$ ) is  
next hop on estimated least-cost  
path to destination ( $z$ )*

# Distance vector algorithm

## key idea:

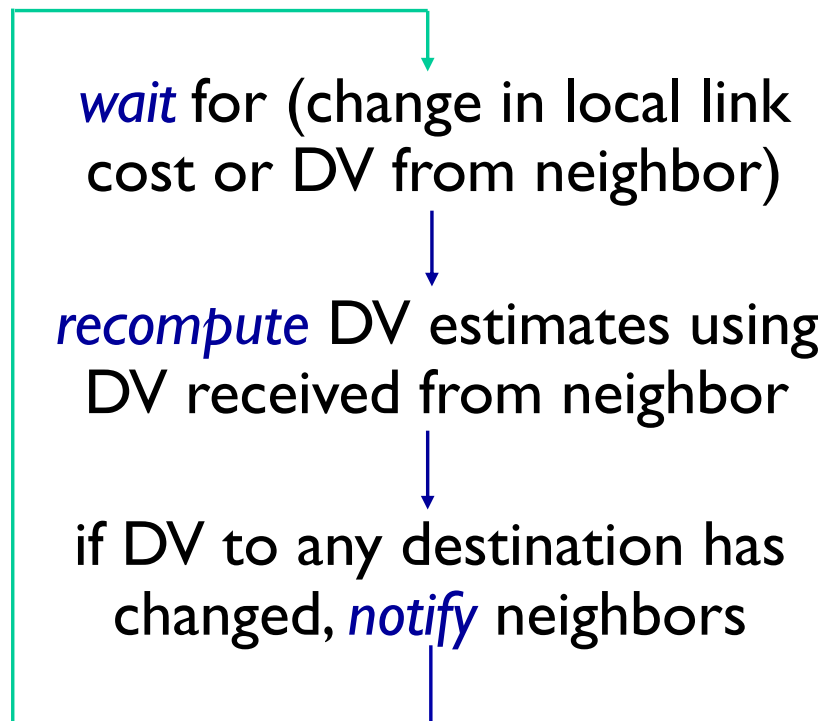

- from time-to-time, each node sends its own distance vector estimate to neighbors
- when  $x$  receives new DV estimate from any neighbor, it updates its own DV using B-F equation:

$$D_x(y) \leftarrow \min_v \{c_{x,v} + D_v(y)\} \text{ for each node } y \in N$$

- under minor, natural conditions, the estimate  $D_x(y)$  converge to the actual least cost  $d_x(y)$

# Distance vector algorithm:

each node:

**iterative, asynchronous:** each local iteration caused by:

- local link cost change
- DV update message from neighbor

**distributed, self-stopping:** each node notifies neighbors *only* when its DV changes

- neighbors then notify their neighbors – *only if necessary*
- no notification received; no actions taken!

# Distance vector: example

$t=0$

- All nodes have distance estimates to nearest neighbors (only)
- All nodes send their local distance vector to their neighbors

DV in a:	
$D_a(a)$	0
$D_a(b)$	8
$D_a(c)$	$\infty$
$D_a(d)$	1
$D_a(e)$	$\infty$
$D_a(f)$	$\infty$
$D_a(g)$	$\infty$
$D_a(h)$	$\infty$
$D_a(i)$	$\infty$

A few asymmetries:

- missing link
- larger cost

# Distance vector example: iteration

t=1

All nodes:

- receive distance vectors from neighbors
- compute their new local distance vector
- send their new local distance vector to neighbors

# Distance vector example: iteration

t=1

All nodes:

- receive distance vectors from neighbors
- compute their new local distance vector
- send their new local distance vector to neighbors

# Distance vector example: iteration

t=1

All nodes:

- receive distance vectors from neighbors
- compute their new local distance vector
- send their new local distance vector to neighbors

# Distance vector example: iteration

t=2

All nodes:

- receive distance vectors from neighbors
- compute their new local distance vector
- send their new local distance vector to neighbors

# Distance vector example: iteration

t=2

All nodes:

- receive distance vectors from neighbors
- compute their new local distance vector
- send their new local distance vector to neighbors

# Distance vector example: iteration

t=2

All nodes:

- receive distance vectors from neighbors
- compute their new local distance vector
- send their new local distance vector to neighbors

# Distance vector example: iteration

.... and so on

Let's next take a look at the iterative *computations* at nodes

# Distance vector example:

**t=1**

- b receives DVs from a, c, e

DV in a:
$D_a(a)=0$
$D_a(b)=8$
$D_a(c)=\infty$

# Distance vector: state information diffusion

Iterative communication, computation steps diffuses information through network:

-   $t=0$  c's state at  $t=0$  is at c only
-   $t=1$  c's state at  $t=0$  has propagated to b, and may influence distance vector computations up to **1** hop away, i.e., at b
-   $t=2$  c's state at  $t=0$  may now influence distance vector computations up to **2** hops away, i.e., at b and now at a, e as well
-   $t=3$  c's state at  $t=0$  may influence distance vector computations up to **3** hops away, i.e., at b,a,e and now at c,f,h as well
-   $t=4$  c's state at  $t=0$  may influence distance vector computations up to **4** hops away, i.e., at b,a,e, c, f, h and now at g,i as well

# Problems with Distance Vector

- A number of problems can occur in a network using distance vector algorithm
- Most of these problems are caused by slow convergence or routers converging on incorrect information
- **Convergence** is the time during which all routers come to an agreement about the best paths through the internetwork
  - whenever topology changes there is a period of instability in the network as the routers converge
- Reacts rapidly to good news, but leisurely to bad news

Link cost changes here

Converges after C receives another update from B

# Will Poison-Reverse Completely Solve the Count-to-Infinity Problem?

Numbers in blue denote the best cost to destination D advertised along the link

# Comparison of LS and DV algorithms

## message complexity

LS:  $n$  routers,  $O(n^2)$  messages sent

DV: exchange between neighbors;  
convergence time varies

## speed of convergence

LS:  $O(n^2)$  algorithm,  $O(n^2)$  messages

- may have oscillations

DV: convergence time varies

- may have routing loops
- count-to-infinity problem

robustness: what happens if router malfunctions, or is compromised?

LS:

- router can advertise incorrect *link* cost
- each router computes only its own table

DV:

- DV router can advertise incorrect *path* cost (“I have a *really* low cost path to everywhere”): black-holing
- each router’s table used by others: error propagate thru network

# Real Protocols

## *Link State*

Open Shortest Path First  
(OSPF)

Intermediate system to  
intermediate system (IS-IS)

## *Distance Vector*

Routing Information  
Protocol (RIP)

Interior Gateway Routing  
Protocol (IGRP-Cisco)

Border Gateway Protocol  
(BGP) - variant

# Quiz: Link-state routing

❖ In link state routing, each node sends information of its direct links (i.e., link state) to \_\_\_\_\_?

- A. Immediate neighbours
- B. All nodes in the network
- C. Any one neighbor
- D. No one

**Answer: B**

[www.pollev.com/salil](http://www.pollev.com/salil)

# Quiz: Distance-vector routing

❖ In distance vector routing, each node shares its distance table with \_\_\_\_\_?

- A. All Immediate neighbours
- B. All nodes in the network
- C. Any one neighbor
- D. No one

**Answer: A**

[www.pollev.com/salil](http://www.pollev.com/salil)

# Quiz: Distance-vector routing

- ❖ Which of the following is true of distance vector routing?
- A. Convergence delay depends on the topology (nodes and links) and link weights
  - B. Convergence delay depends on the number of nodes and links
  - C. Each node knows the entire topology
  - D. A and C
  - E. B and C

**Answer: A**

# Network layer, control plane: outline

5.1 introduction

5.2 routing protocols

- ❖ link state
- ❖ distance vector
- ❖ hierarchical routing

5.6 ICMP: The Internet Control  
Message Protocol

Self study (not on  
exam)

# ICMP: Internet Control Message Protocol

- ❖ Used by hosts & routers to communicate network level information
  - Error reporting: unreachable host, network, port
  - Echo request/reply (used by ping)
- ❖ Works above IP layer
  - ICMP messages carried in IP datagrams
- ❖ ICMP message: type, code plus IP header and first 8 bytes of IP datagram payload causing error

# ICMP: Internet Control Message Protocol

Type	Code	Description
0	0	echo reply(ping)
3	0	dest. network unreachable
3	1	dest host unreachable
3	3	dest port unreachable
3	4	frag needed; DF set
8	0	echo request(ping)
11	0	TTL expired
11	1	frag reassembly time exceeded
12	0	bad IP header

# Traceroute and ICMP

- Source sends series of UDP segments to dest
    - first set has TTL = 1
    - second set has TTL=2, etc.
    - unlikely port number
  - When  $n$ th set of datagrams arrives to  $n$ th router:
    - router discards datagrams
    - and sends source ICMP messages (type 11, code 0)
    - ICMP messages includes IP address of router
  - when ICMP messages arrives, source records RTTs
- stopping criteria:*
- UDP segment eventually arrives at destination host
  - destination returns ICMP “port unreachable” message (type 3, code 3)
  - source stops

# Summary

## ❖ Network Layer: Data Plane

- Overview
- IP

## ❖ Network Layer: Control Plane

- Routing Protocols
  - Link—state
  - Distance Vector
- ICMP
