Queries

A query is a declarative program that retrieves data from a database.

declarative = say what we want, not method to get it

Queries are used in two ways in RDBMSs:

- interactively (e.g. in psq1)
 - the entire result is displayed in tabular format on the output
- by a program (e.g. in a PLpgSQL function)
 - the result tuples are consumed one-at-a-time by the program

SQL is based on the relational algebra, which we discuss elsewhere

< \ \ >>

SQL Query Language

An SQL query consists of a sequence of clauses:

SELECT projectionList

FROM relations/joins

WHERE condition

GROUP BY groupingAttributes

HAVING groupCondition

FROM, WHERE, GROUP BY, HAVING clauses are optional.

Result of query: a relation, typically displayed as a table.

Result could be just one tuple with one attribute (i.e. one value) or even empty

<< / />>>

SQL Query Language (cont)

Functionality provided by SQL ...

Filtering: extract attributes from tuples, extract tuples frm tables

SELECT b,c FROM
$$R(a,b,c,d)$$
 WHERE $a > 5$

Combining: merging related tuples from different tables

```
... FROM R(x,y,z) JOIN S(a,b,c) ON R.y = S.a
```

Summarising: aggregating values in a single column

```
SELECT avg(mark) FROM ...
```

Set operations: union, intersection, difference

COMP3311 20T3 ♦ SQL: Queries on One Table ♦ [3/12]

< /

SQL Query Language (cont)

More functionality provided by SQL ...

Grouping: forming subsets of tuples sharing some property

```
... GROUP BY R.a
```

(forms groups of tuples from R sharing the same value of a)

Group Filtering: selecting only groups satisfying a condition

```
... GROUP BY R.a HAVING max(R.a) < 75
```

Renaming: assign a name to a component of a query

```
SELECT a as name
FROM Employee(a,b,c) e WHERE e.b > 50000
```

COMP3311 20T3 ♦ SQL: Queries on One Table ♦ [4/12]

SQL Query Language (cont)

Schema:

- Students(id, name, ...)
- Enrolments(student, course, mark, grade)

Example SQL query on this schema:

COMP3311 20T3 ♦ SQL: Queries on One Table ♦ [5/12]

SQL Query Language (cont)

How the example query is computed:

- produce all pairs of *Students*, *Enrolments* tuples which satisfy condition (*Students.id = Enrolments.student*)
- each tuple has (id,name,...,student,course,mark,grade)
- form groups of tuples with same (id,name) values
- for each group, compute average mark
- form result tuples (id,name,avgMark)

COMP3311 20T3 ♦ SQL: Queries on One Table ♦ [6/12]

Problem-solving in SQL

Starts with an information request:

• (informal) description of the information required from the database

Ends with:

a list of tuples that meet the requirements in the request

Pre-req: know your schema

Look for keywords in request to identify required data:

- tell me the names of all students...
- how many students failed ...
- what is the highest mark in ...
- which courses are ... (course codes?)

COMP3311 20T3 ♦ SQL: Queries on One Table ♦ [7/12]

Problem-solving in SQL (cont)

Developing SQL queries ...

- relate required data to attributes in schema
- identify which tables contain these attributes
- combine data from relevant tables (FROM, JOIN)
- specify conditions to select relevant data (WHERE)
- [optional] define grouping attributes (GROUP BY)
- develop expressions to compute output values (SELECT)

COMP3311 20T3 ♦ SQL: Queries on One Table ♦ [8/12]

<< / />>>

Problem-solving in SQL (cont)

Example: just the beers that John likes

- which table contains info about beers that are liked?
- Likes(drinker, beers)
- only want tuples where drinker is John (WHERE)
- only want beer names (**SELECT beer**)

... giving ...

select beer from Likes where drinker='John';

COMP3311 20T3 ♦ SQL: Queries on One Table ♦ [9/12]

A view associates a name with a query:

• CREATE VIEW viewName [(attributes)] AS Query

Each time the view is invoked (in a **FROM** clause):

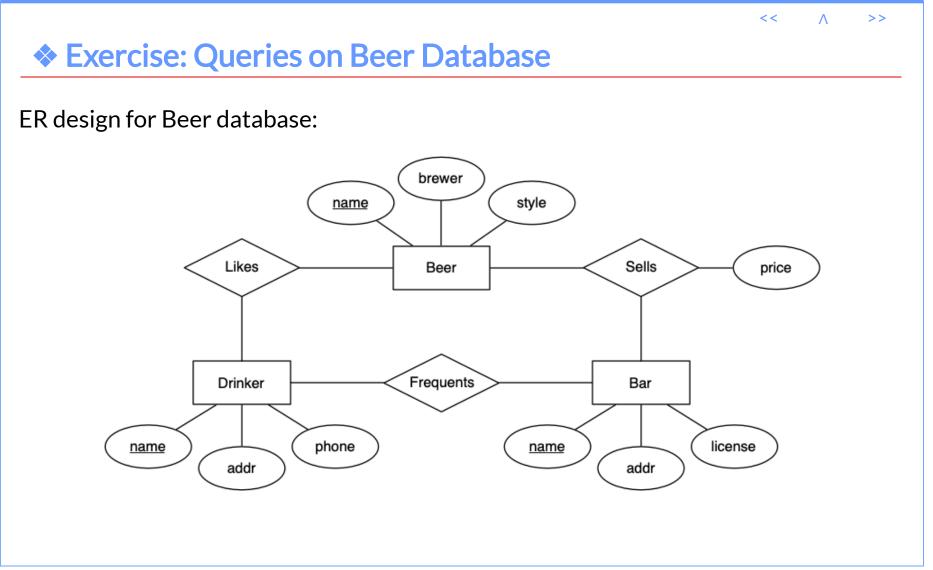

- the *Query* is evaluated, yielding a set of tuples
- the set of tuples is used as the value of the view

A view can be treated as a "virtual table".

Views are useful for "packaging" a complex query to use in other queries.

cf. writing functions to package computations in programs

Λ

Exercise: Queries on Beer Database (cont)

Answer these queries on the Beer database:

- 1. What beers are made by Toohey's?
- 2. Show beers with headings "Beer", "Brewer".
- 3. How many different beers are there?
- 4. How many different brewers are there?
- 5. Which beers does John like?
- 6. Find pairs of beers by the same manufacturer.
- 7. How many beers does each brewer make?
- 8. Which brewers make only one beer?
- 9. Which brewer makes the most beers?
