virtual_memory # Processes

A process is an instance of an executing program

Each process has an execution state, defined by

- current values of CPU registers
- current contents of its (virtual) memory
- information about open files, sockets, etc.

On Unix/Linux:

- each process had a unique process ID (pid)
- positive integer type pid_t defined in unistd.h
- process 0 is effectively part of the operating system
- process 1 (init) used to boot the system
- some parts of operating system may run as processes
- low-numbered processes are typically system-related process started at boot-time

Process Parents

Each process has a parent process

- initially it is the process that created it
- if a process' parent terminates, its parent becomes process 1

Unix provides a range of commandss for manipulating processes, e.g.:

- sh ... for creating processes via object-file name
- ps ... show process information
- w ... show per-user process information
- top ... show high-cpu-usage process information
- kill ... send a signal to a process

Aside: Zombie Process

Zombie Process?

Photo credit: Kenny Louie, Flickr.com

Aside: zombie Processes

- a process can't terminate until its parent is notified
- if exit() called, operating system sends SIGCHLD signal to parent
- exit() will not return until parent handles SIGCHLD
- Zombie process = exiting process waiting for parent to handle SIGCHLD
- all processes become zombies until SIGCHLD handled
- bug in parent that ignores SIGCHLD creates long-term zombie processes
 - wastes some operating system resources
- Orphan process = a process whose parent has exited
 - when parent exits, orphan is assigned pid=1 (init) as its parent
 - init should always handles SIGCHLD when process exits

Multi-Tasking

On a typical modern operating system

- multiple processes are active "simultaneously" (multi-tasking)
- operating systems provides a virtual machine to each processs
 - each process executes as if the only process running on the machine
 - e.g. each process has its own address space (N bytes, addressed 0..N-1)

When there are multiple processes running on the machine

- each process uses the CPU until *pre-empted* or exits
- then another process uses the CPU until it too is pre-empted
- eventually, the first process will get another run on the CPU

time	
Process 1	
Process 2	
Process 3	

Overall impression: three programs running simultaneously

Processes

What can cause a process to be pre-empted?

- it runs "long enough" and the OS replaces it by a waiting process
- it needs to wait for input, or output or . . .

On pre-emption ..

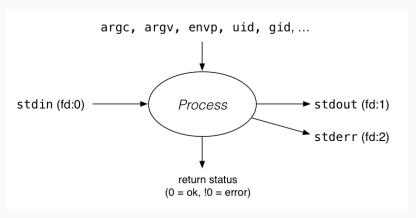

- the process's entire state must be saved
- the new process's state must be restored
- this change is called a context switch
- context switches are expensive

The operating system's process scheduling attempts to:

- fairly sharing the CPU(s) among competing processes
- minimize response delays (lagginess) for interactive users
- meet other real-time requirements (e.g. self-driving car)
- minimize number of expensive context switches

Unix/Linux Processes

Environment for processes running on Unix/Linux systems

Process-related Unix/Linux Functions/System Calls

- posix_spawn() ... create a new process, see also
 - clone() ... duplicate current process address space can be shared to implement threads only use clone if posix_spawn can't do what you want
- fork() ... duplicate current process do not use in new code
- execvp() ... replace current process
- system() popen() ... create a new process via a shell (unsafe)
- exit() ... terminate current process, see also
 - _exit() ... terminate current process immediately atexit functions not be called: stdio buffers not flushed
- getpid() ... get process ID
- getpgid() ... get process group ID
- waitpid() ... wait for state change in child process

posix_spawn() - run a new process

- creates new process, running program at path
- argv specifies argv of new program
- envp specifies environment of new program
- *pid set to process id of new program
- file_actions specifies file actions to be performed before running program
 - can be used to re-direct stdin or stdout to file or pipe
 - advanced topic
- attrp specifies attributes for new process

Simple example using posix_spawn() to run /bin/date

```
pid_t pid;
extern char **environ;
char *date_argv[] = {"/bin/date", "--utc", NULL};
// spawn "/bin/date" as a separate process
if (posix spawn(&pid, "/bin/date", NULL, NULL, date argv, environ)
    perror("spawn");
   exit(1):
// wait for spawned processes to finish
int exit status;
if (waitpid(pid, &exit_status, 0) == -1) {
   perror("waitpid");
   exit(1);
}
printf("/bin/date exit status was %d\n", exit_status);
```

fork() - clone yourself

```
#include <sys/types.h>
#include <unistd.h>
pid_t fork(void);
```

- creates new process by duplicating the calling process
- new process is the *child*, calling process is the *parent*
- child has a different process ID (pid) to the parent
- in the child, fork() returns 0
- in the parent, fork() returns the pid of the child
- if the system call fails, fork() returns -1
- child inherits copies of parent's address space and open file descriptors
- do not use in new code use posix_spawn instead
 - fork appears simple but prone to subtle bugs

Simple example of using fork()

```
// fork creates 2 identical copies of program
// only return value is different
pid_t pid = fork();
if (pid == -1) {
     perror("fork"); // print why the fork failed
} else if (pid == 0) {
    printf("I am the child because fork() returned %d.\n", pid);
} else {
    printf("I am the parent because fork() returned %d.\n", pid);
source code for fork c
$ dcc fork.c
$ a.out
I am the parent because fork() returned 2884551.
I am the child because fork() returned 0.
$
```

12

execvp() - replace yourself

- argv specifies argv of new programmost of the current process is reset
 - e.g. new virtual address space is created, signal handlers reset
- new process inherits open file descriptors from original process
- on error, returns -1 and sets errno
- if successful, does not return

Simple example of using exec()

```
char *echo_argv[] = {"/bin/echo", "good-bye", "cruel", "world", NULL};
execv("/bin/echo", echo_argv);
// if we get here there has been an error
perror("execv");
source code for exec.c

$ dcc exec.c
$ a.out
good-bye cruel world
```

Simple example using fork() and exec() to run /bin/date

```
pid_t pid = fork();
if (pid == -1) {
     perror("fork"); // print why fork failed
} else if (pid == 0) { // child
    char *date argv[] = {"/bin/date", "--utc", NULL};
    execv("/bin/date", date_argv);
    perror("execvpe"); // print why exec failed
} else { // parent
    int exit_status;
    if (waitpid(pid, &exit status, 0) == -1) {
        perror("waitpid");
        exit(1);
    }
    printf("/bin/date exit status was %d\n", exit status);
```

system() - convenient but unsafe way to run another program

```
#include <stdlib.h>
int system(const char *command);

    runs command via /bin/sh

    waits for command to finish and returns exit status

    convenient but brittle and highly vulnerable to security exploits

    use for quick debugging and throw-away programs only

// run date --utc to print current UTC
int exit_status = system("/bin/date --utc");
printf("/bin/date exit status was %d\n", exit status);
return 0:
source code for system.c
```

running Is -Id via posix_spawn

source code for IsId spawn.c

```
char *ls argv[argc + 2];
ls argv[0] = "/bin/ls";
ls_argv[1] = "-ld";
for (int i = 1; i <= argc; i++) {
    ls argv[i + 1] = argv[i];
}
pid t pid;
extern char **environ;
if (posix_spawn(&pid, "/bin/ls", NULL, NULL, ls_argv, environ) != (
    perror("spawn");
    exit(1);
```

running Is -Id via posix_spawn

```
int exit_status;
if (waitpid(pid, &exit_status, 0) == -1) {
    perror("waitpid");
    exit(1);
}
// exit with whatever status ls exited with
return exit_status;
```

running Is -ld via system

source code for IsId system.c

```
char *ls = "/bin/ls -ld";
int command length = strlen(ls);
for (int i = 1; i < argc; i++) {
    command_length += strlen(argv[i]) + 1;
}
// create command as string
char command[command_length + 1];
strcpy(command, ls);
for (int i = 1; i <= argc; i++) {
    strcat(command, " ");
    strcat(command, argv[i]);
int exit status = system(command);
```

getpid & getppid

```
#include <sys/types.h>
#include <unistd.h>
pid_t getpid(void);
pid_t getppid(void);
```

- getpid returns the process ID of the current process
- getppid returns process ID of the the parent of current process

waitpid

```
#include <sys/types.h>
#include <sys/wait.h>

pid_t waitpid(pid_t pid, int *wstatus, int options);
pid_t wait(int *wstatus);
```

- waitpid pauses current process until process pid changes state
 - where state changes include finishing, stopping, re-starting, . . .
- ensures that child resources are released on exit
- special values for pid ...
 - if pid = -1, wait on any child process
 - if pid = 0, wait on any child in process group
 - if pid > 0, wait on the specified process

```
pid_t wait(int *status)
```

- equivalent to waitpid(-1, &status, 0)
- pauses until one of the child processes terminates

waitpid

More on waitpid(pid, &status, options)

- status is set to hold info about pid
 - e.g. exit status if pid terminated
 - macros allow precise determination of state change (e.g. WIFEXITED(status), WCOREDUMP(status))
- options provide variations in waitpid() behaviour
 - default: wait for child process to terminate
 - WNOHANG: return immediately if no child has exited
 - WCONTINUED: return if a stopped child has been restarted

For more information: man 2 waitpid

linux/environment variables

- when linux/unix program are passed environment variables
- *environment variables* are array of strings of form name=value
- array is NULL-terminated
- access via global variable environ
- many C implementation also provide as 3rd parameter to main:

```
int main(int argc, char *argv[], char *env[])
```

- most program use getenv & setenv to access environment variables
- can access environment variables directly, eg:

```
// print all environment variables
extern char **environ;
for (int i = 0; environ[i] != NULL; i++) {
    printf("%s\n", environ[i]);
}
```

accessing an environment variable with getenv

source code for get status.c

```
#include <stdlib.h>
char *getenv(const char *name);

• search environment variable array for name=value
• returns value
• returns NULL if name not in environment variable array

// print value of environment variable STATUS
char *value = getenv("STATUS");
printf("Environment variable 'STATUS' has value '%s'\n", value);
```

setting an environment variables with setenv

```
#include <stdlib.h>
int setenv(const char *name, const char *value, int overwrite);

    adds name=value to environment variable array

 • if name in array, value changed if overwrite is non-zero
// set environment variable STATUS
setenv("STATUS", "great", 1);
char *getenv_argv[] = {"./get_status", NULL};
pid t pid;
extern char **environ;
if (posix_spawn(&pid, "./get_status", NULL, NULL,
    getenv argv, environ) != 0) {
    perror("spawn");
    exit(1);
```

changing behaviour with an environment variable

```
pid_t pid;
char *date argv[] = { "/bin/date", NULL };
char *date_environment[] = { "TZ=Australia/Perth", NULL };
// print time in Perth
if (posix spawn(&pid, "/bin/date", NULL, NULL, date argv,
                date environment) != 0) {
    perror("spawn");
    return 1:
int exit status;
if (waitpid(pid, &exit status, 0) == -1) {
    perror("waitpid");
   return 1;
}
printf("/bin/date exit status was %d\n", exit status);
```

exit() - terminate yourself

```
#include <stdlib.h>
void exit(int status);
```

- triggers any functions registered as atexit()
- flushes stdio buffers; closes open FILE *'s
- terminates current process
- a SIGCHLD signal is sent to parent
- returns status to parent (via waitpid())
- any child processes are inherited by init (pid 1)

Also void _exit(int status)

- terminates current process without triggering functions registered as atexit()
- stdio buffers not flushed

pipe() - stream bytes between processes

```
#include <unistd.h>
int pipe(int pipefd[2]);
```

- a pipe is a unidirectional byte stream provided by operating system
- pipefd[0] set to file descriptor of read end of pipe
- pipefd[1] set to file descriptor of write end of pipe
- bytes written to pipefd[1] will be read from pipefd[1]
- child processes (by default) inherit file descriptors including for pipe
- parent can send/receive bytes (not both) to child via pipe
- parent and child should both close the pipe file descriptor they are not using
 - e.g if bytes being written (sent) parent to child
 - parent should close read end pipefd[0]
 - child should close write end pipefd[1]
- pipe (and other) file descriptors can be used with stdio via **fdopen**

popen() - convenient but unsafe way to set up pipe

```
#include <stdio.h>
FILE *popen(const char *command, const char *type);
int pclose(FILE *stream);
```

- runs command via /bin/sh
- if type is "w" pipe to stdin of command created
- if type is "r" pipe from stdout of command created
- FILE * stream returned get then use fgetc/fputc etc
- NULL returned if error
- close stream with pclose (not fclose)
 - pclose waits for command and returns exit status
- convenient but brittle and highly vulnerable to security exploits
- use for quick debugging and throw-away programs only

popen() - capturing output from a process

```
// popen passes string to a shell for evaluation
// brittle and highly-vulnerable to security exploits
// popen is suitable for quick debugging and throw-away programs or
FILE *p = popen("/bin/date --utc", "r");
if (p == NULL) {
   perror("");
   return 1;
char line[256];
if (fgets(line, sizeof line, p) == NULL) {
    fprintf(stderr, "no output from date\n");
   return 1;
}
printf("output captured from /bin/date was: '%s'\n", line);
pclose(p); // returns command exit status
```

popen() - sending input to a process

```
int main(void) {
   // popen passes command to a shell for evaluation
   // brittle and highly-vulnerable to security exploits
   // popen is suitable for quick debugging and throw-away program
   // tr a-z A-Z - passes stdin to stdout converting lower case to
   FILE *p = popen("tr a-z A-Z", "w");
   if (p == NULL) {
       perror("");
        return 1;
   fprintf(p, "plz date me\n");
   pclose(p); // returns command exit status
   return 0:
```

posix_spawn and pipes (advanced topic)

```
int posix_spawn_file_actions_destroy(
   posix_spawn_file_actions_t *file_actions);
int posix_spawn_file_actions_init(
   posix_spawn_file_actions_t *file_actions);
int posix_spawn_file_actions_addclose(
   posix_spawn_file_actions_t *file_actions, int fildes);
int posix_spawn_file_actions_adddup2(
   posix_spawn_file_actions_t *file_actions, int fildes,
   int newfildes);
```

- functions to combine file operations with posix_spawn process creation
- awkward to understand & use but robust
- example: capturing output from a process source code for spawn_read_pipe.c
- example: sending input to a process source code for spawn_write_pipe.c
